

Assignment - 2

A. Consider the boundary value problem discussed in the class:

$$u_{,xx}(x) + f(x) = 0, \quad \text{on }]0.1[, \quad (1)$$

$$u(1) = g, \quad (2)$$

$$-u_{,x}(0) = h. \quad (3)$$

Assume $f(x) = qx$ where q is a constant and $g = h = 0$.

1. Employing the linear finite element space with equally spaced nodes, set up and solve the Galerkin-Finite Element equations for $n = 4$, i.e. $h = 1/4$. This has been done in the class for $n = 1, 2$. However, please redo them to check the final numbers.
2. Is the stiffness matrix banded? What is the consequence of boundary terms (g and h) on the bandedness?
3. Let $re_{,x} = |u_{,x}^h - u_{,x}| / (q/2)$ denote the relative error in $u_{,x}$. Compute $re_{,x}$ at the midpoints of the 4 elements. They should be all equal. This was also true for $n = 2$ (Check!).
4. Employing the data presented in class for $h = 1$ and $h = 1/2$, plot $\ln(re_{,x})$ versus $\ln(h)$.
5. What is the significance of the slope and the the y-intercept?

B. For the same problem, as described in part A, write a computer program to assemble the element level stiffness matrices and force vectors. Solve the matrix equation system using a linear equation solver (you can use a library or any other available program, for solving $\mathbf{A} \mathbf{x} = \mathbf{b}$). Plot the solution and the slope. Compute the relative error for $n = 10$, $n = 50$ and $n = 100$. Calculate the slope as was done in the previous part. Comment on the results.
